- **Network** of public and private research institutes
- Funded by the **Italian** Ministries: MIUR (University & Research), MATTM (Environment) and MEF (Economy & Finance).
- **IPCC focal point** for Italy
Mission and Network

Investigate and model the climate system and its interaction with society to provide reliable, rigorous, and timely scientific results to stimulate sustainable growth, protect the environment and to develop science-driven adaptation and mitigation policies in a changing climate.

CMCC network
The CMCC Divisions

ClimateServices (SERC)

Activities:

• Production of climate predictions at seasonal to decadal time-scale and climate change projections (global scale, regional focuses).

• Communication of the results and information obtained to a broad range of users: decision makers and stakeholders, political bodies and public administration, researchers from other disciplines.

• Coordinate research on adaptation policies to climate change and provide technical and scientific support to the institutions for multilateral negotiation processes in the field of climate change (EU, IPCC, UNFCCC).
The CMCC Seasonal Prediction System represents the various components of the Earth system. Its initial state is determined by a long integration to reach a condition of equilibrium. From this state, the model evolves driven by its physics and boundary conditions associated, in particular the radiative forcing.

The CMCC Seasonal Prediction System is initialized with the “closest to reality” state of the ocean (SPSv1) and land-atmosphere (SPSv2), which drive the model towards a state affected by the initialization itself other than boundary conditions and its internal physics.
Uncertainties on initial data could be large. To supply for this issue: ensemble technique with perturbed initial conditions.

Validation of the CMCC-SPS

Tsurf Anomaly Correlation (ACC) lead time 1

ACC is a measure of the skill of the system, indicating the correlation between forecast and ERAinterim reanalyses between 1989-2010. Values close to 1 => high predictability.

• Predictability is higher in the Tropics and in the oceans than on continents.
• High skill in the ENSO area and teleconnected regions.
• Good skill in the Northern Atlantic region, particularly in the winter and the spring.
Validation of the CMCC-SPSv2

The ENSO signal is well predicted by the CMCC-SPS, with anomaly correlation coefficients higher than 95% in the NINO3.4 region.
Validation of the CMCC-SPS

Predictability of the West African Monsoon

\[ \text{WAMI} = u_{850\text{hPa}} - u_{200\text{hPa}} \]

Fontaine et al., 1995 J.Clim

CMCC-SPSv2 intercepts the interannual variability of Monsoon winds.
CC model/obs = 0.66

Nevertheless, precipitation during the summer turns out to be too weak and to penetrate too much in inland.
Results from three different versions of the CMCC-SPS

The importance of an accurate ocean

Assimilated Ocean IC
a) Start date May 1  b) Start date November 1

Ocean IC with no assimilation
c) Start date May 1  d) Start date November 1

Assimilated IC vs. no Assimilation
e) Start date May 1  f) Start date November 1

ACC for the start date of May and November (SPSv1) which assimilates observed profiles of temperature and salinity through the water column of the global configuration of the OPA8.2 ocean model.

Comparison with an AMIP-like initialization, performed by prescribing observed SST (HadISST1.1; Rayner et al. 2003) boundary forcing to the atmospheric model.

From Alessandri et al., 2010

No assimilation

Ocean analysis

Assimilation (SPSv1)

Contour = 0.04 Pa

Evolution of the heat content anomaly (shaded) and zonal wind stress anomaly (contour) averaged between 5S and 5N. Forecast anomalies are ensemble means.

From Alessandri et al., 2010
SPS2 provides a remarkable improvement of the forecast skill at lead-season 0, where the effect of initialization is clearly reflected. Continental areas benefit the most from the more realistic initial state, but enhancements are mainly lost after lead-season 0. In the ocean instead

- northern Pacific, long-lasting skill improvements due to strong air-sea coupling in the region during the fall. SSTAs force a PNA pattern response, atmospheric reaction could in turn change SSTs
- ENSO region in May, and ETA in November, when the effect of atmosphere is stronger. In the season of major upwelling, SSTs are mostly determined by upwelling of deep water, which does not change in the two experiments
The introduction of land-atmosphere initial condition demonstrates an important and potentially predictable impact on the forecasts of equatorial Pacific SST (particularly in May), either as a result of the intra-seasonal stochastic component of the atmospheric initial state (Shi et al., 2011), or for the amplification of initial condition error in such a coupled system (Hudson et al., 2011).
Separating the contribution of atmosphere and land surface initial state

The SPSv1.5 experiment maintains the atmosphere initial conditions, but excludes the prior knowledge of land-surface state.

Differences in ACC are larger on continents than over ocean, and improvements carried by SPSv2 are season and region dependent. Sometimes better land surface IC degrade the quality of the forecast, most likely due to the initialization technique (Materia et al. 2013)
Anomaly correlation for the three different versions of CMCC-SPS
The seasonal forecast bulletin

CMCC-SPSv2.0 Seasonal Forecast
August 2012

SUMMARY

In the upcoming six months a permanent warm conditions from the current state is predicted for Equatorial Pacific. The extra-tropical North Pacific will be warmer than the average in the western sector, colder alongside the American coast. Below normal temperature will characterize Western Canada and Australia. While a transition from the current warm state to colder conditions is predicted for North-Western Europe. Warm conditions for Northern Asia is predicted. Central and West Africa, East Indian Ocean, Australia, Indonesia and Philippines are expected to undergo a dry season, while wet conditions are predicted for Western Central Pacific.

This bulletin is based on model simulations performed with the Seasonal Prediction System developed at CMCC (CMCC-SPSv2). A 6-month forecast is produced every month starting from a synthesis of the current state of the ocean and the atmosphere. Both deterministic and probabilistic predictions are provided for global precipitation and surface temperature fields. A regional focus on the equatorial Pacific (NiNo3 region) is also supplied.

Important: Seasonal Forecasts do not provide any detailed spatial information, but only give a general sense of the character of the season by providing a forecast of seasonal temperature and rainfall anomalies probability of occurrence.

- Quasi-monthly product
- Still a scientific exercise (not operational yet)
- It provides updates about actual situation, verification versus the latest season, and the forecast for the next one
- Available upon request, on-line soon
